Abstract

A new species of Lumbrineridae, Augeneria profundicola sp. nov. is described based on one specimen taken from 950 m depth on muddy bottom off Gökçeada Island (northern Aegean Sea). This new species is characterized by having seven small nuchal antennae arranged in a circle line on the prostomium and bidentate maxilla II. The morphological features of this species were compared with those of all Augeneria species described so far. A taxonomic key to all Augeneria species is also provided.

Keywords: Lumbrinerid, description, taxonomy, deep sea, northern Aegean Sea.

Introduction

The family Lumbrineridae Shmarda, 1861 is represented by 10 genera (Abyssoninina Orensanz, 1990; Augeneria Monro, 1930; Gallardoneris Carrera-Parra, 2006; Hilbigneris Carrera-Parra, 2006; Lumbricalus Frame, 1992; Lumbrinerides Orensanz, 1973; Lumbrineriopsis Orensanz, 1973; Lumbrineris Blainville, 1828; Ninoe Kinberg, 1865; Scoletoma Blainville, 1828) and 33 species in the Mediterranean (Coll et al., 2010; D’Alessandro et al., 2014; Bertasi et al., 2014; Gómez et al., 2015). A total of 17 species belonging to 7 genera (Hilbigneris, Lumbricalus, Lumbrinerides, Lumbrineriopsis, Lumbrineris, Ninoe and Scoletoma) were found along the coasts of Turkey (Çinar et al., 2014). Two lumbrinerid species, namely, Lumbrineris perkinsi (Carrera-Parra, 2001) and Scoletoma debilis (Grube, 1878), were considered as alien species in the Mediterranean Sea. Lumbrineris perkinsi was regarded as a Lessepsian invader (i.e. a species that has migrated from the Red Sea to the Mediterranean via the Suez Canal) and densely occurred along the southern coast of Turkey (Çinar, 2009). Scoletoma debilis was first reported from the Sea of Marmara by Rullier et al. (2006) from the Bay of Biscay, Atlantic Ocean at 480-580 m), A. tentaculata Monro, 1930 (from Signy Island, Antarctic Ocean at 244-344 m) and A. verdis Hutchings and Murray, 1984 (from the Tasman Sea, Pacific Ocean at 4-12 m). The validity of A. dayi within the genus Augeneria seems to be questionable, as it lacks composite hooded hooks on the parapodia. The genus with antennae on the prostomium and lacking composite hooded hooks are Kiwuita Mohammad, 1973; Cenogenus Chamberlin, 1919 and Sergioneris Carrera-Parra, 2006. The original description of A. dayi from Sri Lanka by de Silva (1965) was poor, lacking a proper description of the morphology of the maxillary apparatus, which is one of the diagnostic characters of the genus Augeneria. Therefore, a re-description of the species, based on type specimens, is required to determine which genus it in fact belongs to. Orensanz (1973; 1990) mentioned that Lumbrineris meteorana Augener, 1931 seems to be morphologically similar to Augeneria in having a large and rounded MIV with a dark edge and a pale middle part like the other species of Augeneria. However, it differs from the Augeneria species in lacking nuchal antennae and a divergent mandible. Therefore, in this study, this species was not considered within Augeneria, and its taxonomic
placement requires re-consideration within the genus. Among Augeneria species, only A. tentaculata has been reported from the Mediterranean Sea (Alboran Sea) at 1491 m depth (Miura, 1980).

In this paper, we describe a new species of Augeneria, Augeneria profundicola sp. nov., based on one specimen collected in deep-water off Gökçeada (northern Aegean Sea). Also, a taxonomic key to all the species of the genus is provided.

Material and Methods

One specimen of Augeneria profundicola sp. nov. was collected by a baited trap set on a muddy bottom at 950 m depth off Gökçeada Island in the northern Aegean Sea (40°19′19″N-25°38′35″E) in October 2014 (Fig. 1). In the field, the specimen was fixed with 4% formaldehyde solution. At the laboratory, the specimen was washed with tap water and then preserved in 70% ethanol.

In order to examine details of both the maxillae and the mandible under a compound microscope, an anterodorsal dissection was made to extract the maxillary apparatus. The body length, length of the head and the first 10 chaetigerous segments (L10) and the width at chaetiger 10 (excluding parapodia and chaetae) were measured with an ocular micrometer. Photographs of the general view of the specimen were taken using a digital camera (Nikon, P7000) attached to a stereo-microscope and the chaetal images were taken by a digital imaging system (Nikon, DS-Fi2) installed on a compound microscope using a DIC (Differential Interference Contrast) attachment.

The holotype of Augeneria profundicola sp. nov. was deposited at the Museum of the Faculty of Fisheries (ESFM), Ege University, Turkey.

Taxonomic Account

Class Polychaeta Grube, 1850
Order Eunicida Dales, 1962
Family Lumbrineridae Schmarda, 1861
Genus Augeneria Monro, 1930
Augeneria profundicola sp. nov.
(Figures 2-4)

Description. Holotype incomplete with 55 chaetigers, 34.6 mm long, 1.7 mm wide, L10= 5.7 mm. Body cylindrical, pale pink coloured, slightly tapering posteriorly. Prostomium conical, as long as wide, with seven small nuchal antennae arranged in a circle line (Figs. 2A-C, Fig. 3A). Peristomium shorter (0.65 mm) than prostomium (0.9 mm); with two rings, anterior ring (0.45 mm) more than twice as long as posterior ring (0.2 mm); separation between rings distinct dorsally and ventrally. All parapodia well developed; first three parapodia smaller than following ones. Anterior parapodia approximately as long as 1/7 of anterior segment’s width; posterior parapodia as long as 1/5 of posterior segment’s width. Prechaetal lobe inconspicuous on parapodia 1–9; like a conical projection on parapodia 10 to 14; digitiform, as long as postchaetal lobe from parapodia 14 towards posterior.
end (Figs. 3B-D; Figs. 4A-C). Postchaetal lobes well-developed in all parapodia; conical on first three parapodia; digitiform, longer than prechaetal lobe between parapodia 4 and 14; digitiform, as long as prechaetal lobe from parapodia 14 towards posterior end (Figs. 3B-D; Figs. 4A-C). Chaetae including composite multidentate hooded hooks, simple multidentate hooded hooks and limbates. Composite multidentate hooded hooks present on chaetigers 1–18, having short blade (~400 µm) and a distinct main fang with 4–5 teeth of similar size (Fig. 3F, Fig. 4D). Simple multidentate hooded hooks present from chaetiger 19 to posterior end, with a short hood and distinct main fang with up to 6 teeth (Fig. 3G, Fig. 4E). Dorsal and ventral limbate chaetae only present between chaetiger 1 and 18 (Fig. 3H, Fig. 4F). Aciculae yellow, aristate, up to three in anterior chaetigers and one and reddish in posterior ones (Figs. 3B-C). Maxillary apparatus with four pairs of maxillae (Fig. 2D; Fig. 3E); maxillary carriers slightly longer than MI; MI forceps-like with expanded basal part; MII with only two teeth; MIII edentate, arcuate; MIV edentate with a whitish central area and pigmented peripheral line. Mandible divergent at both its anterior and posterior ends.

**Etymology.** The name was chosen to indicate the deep water existence of the species from the Latin pro-fundus meaning deep and the suffix cola for dweller.

**Type Locality.** Gökçeada Island, Aegean Sea.

**Discussion.** Augeneria species mainly occur on soft substratum in deep-waters. They are generally found at depths deeper than 100 m. The species already reported from depths deeper than 500 m are *A. algida* and *A. riojai*. However, *A. verdis* was found in shallow-water benthic environments (sandy mud and shell fragments at 7-12 m depth) in the Tasman Sea (Hutchings and Murray, 1984).

The main differences between *A. profundicola* sp. nov., and the other species of *Augeneria* are shown in Table 1. The number of nuchal antennae on the prostomium is one of the diagnostic characters that are used to distinguish the species within the genus. Five species (*Augeneria albidentata*, *A. algida*, *A. bidens*, *A. tentaculata* and *A. verdis*) have only three antennae on the prostomium, whereas *A. polydentata* has a prostomium with seven nuchal antennae and *A. riojai* with eight nuchal antennae. *Augeneria profundicola* sp. nov. resembles *A. polydentata* and *A. riojai* in having several small nuchal antennae on the posterior part of the prostomium, but it mainly differs from them in having bidentate MII. *Augeneria polydentata* sp. nov. also close to *A. albidentata* by having bidentate MII but differs in having seven nuchal antennae. In addition, *A. profundicola* sp. nov. has yellow (anterior) and reddish (posterior) aciculae and composite hooded hooks with distinct main fang with 5 short teeth of similar size, whereas *A. riojai* has black aciculae and composite hooded hooks with 7 short teeth of similar size, and *A. polydentata* has yellow aciculae and composite hooded hooks with 7 short teeth of similar size. Moreover, the nuchal antennae on the prostomium of *A. riojai* and *A. polydentata* are arranged in two rows, but those of *A. profundicola* sp. nov. are arranged in a circle. Although *Augeneria profundicola* sp. nov. has composite hooks with short blade like *A. riojai*, *A. tentaculata* and *A. verdis*, the new species has composite hooks with distinct main fang before smaller teeth differently from others.

**Key to all species of Augeneria**

1-MII with two teeth ..................................................... 2
   MII with three teeth .................................................. 3
2-Prostomium with three nuchal antennae;
   postchaetal lobes digitiform in anterior and posterior parapodia .................. *Augeneria albidentata*
   Prostomium with seven nuchal antennae;
   postchaetal lobes conical on first three parapodia; digitiform on remaining
   parapodia .................. *Augeneria profundicola* sp. nov.
3-Prostomium with three nuchal antennae .................. 4
   Prostomium with more than three nuchal antennae .... 7
4-Composite hooded hooks with short blade .............. 5
   Composite hooded hooks with long blade .................. *Augeneria algida*
5-Postchaetal lobes always digitiform in anterior parapodia .................. *Augeneria verdis*
   Postchaetal lobes otherwise in anterior parapodia ..... 6
6-Postchaetal lobes rounded and digitiform in anterior parapodia; prechaetal lobes short on anterior parapodia and slightly longer on posterior parapodia .................. *Augeneria bidens*
   Postchaetal lobes subtriangular in anterior parapodia; prechaetal lobes truncated along body .................. *Augeneria tentaculata*
   7-Acicula black .................. *Augeneria riojai*
   Acicula yellow .............. *Augeneria polydentata*
