KEYWORDS	ABSTRACT
Gratitude S-GRAT Reliability Validity Personality Happiness Life Satisfaction	Gratitude is a psychological notion that has been associated with numerous beneficial outcomes for individuals and communities. The Short Gratitude Resentment and Appreciation Test (S-GRAT), one of the most widely used measure to detect trait gratitude, comprises three subscales that assess lack of a sense of deprivation, appreciation for simple pleasures, and appreciation of others. The present study tested the psychometric properties of the Greek version of the S-GRAT scale. Using a sample of 681 adults from the general population and a smaller separate sample of fifty individuals we found that the scale demonstrated good internal consistency and high test-retest reliability. Explanatory and confirmatory factor analyses confirmed the original three-dimensional scale structure. Convergent and discriminant validity tests found S-GRAT-Gr total score was significantly correlated with Agreeableness, Intellect, Extraversion, Emotional Stability and Conscientiousness. S-GRAT-Gr also had positive correlations with the Gratitude Questionnaire (GQ-6), the Subjective Happiness Scale and the Satisfaction With Life Scale. S-GRAT-Gr score was found to have a unique impact on Life Satisfaction and Happiness beyond the basic taxonomies of personality and also beyond the GQ-6. Results indicate that the Greek version of the Revised Short Gratitude, Resentment, and Appreciation Test (S-GRAT-Gr) is a reliable and valid instrument for assessing dispositional gratitude in the Greek context.

Introduction

Gratitude is no longer ‘one of the neglected virtues in psychology’ (Solomon, 2004, p.vii; Watkins et al., 2003, p.431). In recent years, gratitude has attracted considerable attention in several psychology sub-fields. Yet, there has been a lack of agreement about the nature of the construct (Wood et al., 2010) and gratitude has been described in a variety of ways both as a trait and as a state (Rosenberg, 1998). Although the number of studies on gratitude has increased in the last twenty years, there is still a need for research on aspects of gratitude worldwide. In Greece, research on gratitude is still scarce. This is problematic given the increasing evidence that positive psychological intervention, in gratitude particular, varies in different cultural contexts (Ng & Lim, 2019; Titova et al., 2017). Reliable and valid measurement tools of gratitude are essential to conduct comparable and repeatable studies. To date, there is a lack of standardized measures of gratitude in the Greek context. Therefore,

the present work adapted and validated in Greek the Short Gratitude, Resentment, and Appreciation Test (S-GRAT).

Conceptualization and benefits of gratitude

There is limited consensus regarding the theoretical structure of the concept of gratitude (Hammer & Brenner, 2019). Some consider gratitude as a unitary concept, while others disagree in that respect (Diessner & Lewis, 2007; McCullough et al., 2002; Watkins et al., 2003). Moreover, there is a conceptual distinction between gratitude and appreciation and there is a polyphony about whether gratitude “must” include a distinct benefactor (Adler & Fagley, 2005; Lambert et al., 2009; Steindl-Rast, 2004). At the trait level, gratitude is known as a grateful disposition (Emmons & McCullough, 2004), referring to “a generalized tendency to recognize and respond with grateful emotion to the roles of other people's benevolence in the positive experiences and outcomes one has and to respond with grateful feelings” (McCullough et al., 2002, p. 112). It is also defined as “a life orientation towards noticing and appreciating the positive in life” (Wood et al., 2010, p. 892).

Gratitude is positively associated with psychological well-being and happiness (Emmons et al., 2019; Hemarajareswari & Gupta, 2021), life satisfaction (Toepfer et al., 2012), empathy (Lasota et al., 2022), social relationships (Algoe et al., 2008; Lambert et al., 2010), optimism (Froh et al., 2009), religiosity/spirituality (McCullough et al., 2002), teamwork and altruism (Dik et al., 2015) among other positive outcomes. People who feel grateful have lower levels of depression (Lodice et al., 2021), stress (Manita et al., 2020), antisocial thinking/acting (Froh et al., 2009), envy (Mao et al., 2021), anger when hurt by others (McCullough et al., 2002). There is also a relationship between dispositional gratitude and personality, as measured by personality tests such as the Big Five Mini-Markers scale and the Revised NEO Personality Inventory (NEO PI-R) (McCullough et al., 2002; Wood et al., 2008). Higher levels of gratitude have been found to be positively associated with the personality traits of Agreeableness (McCullough et al., 2002; Wood et al., 2008; Wood et al., 2010), Extraversion and Conscientiousness, (Szcześniak et al., 2020), Openness (Alvi et al., 2022; Wood et al., 2008) and negatively related to Neuroticism (Szcześniak et al., 2020).

Measuring gratitude

Acknowledging the benefits of gratitude, several instruments have been developed to measure it. The Gratitude Questionnaire-Six Item Form (GQ-6) is a 6-item scale, which has shown good reliability and validity (Wood et al., 2009) and it assesses grateful emotions (McCullough et al., 2002). It measures span, frequency, intensity and density of gratitude and primarily focuses on the unidimensional emotional component of gratitude. Authors consider gratitude as an affective trait, named as a disposition toward gratitude (McCullough et al., 2002). Adler and Fagley (2005) conceptualized gratitude as a subordinate facet of appreciation and limited gratitude to instances where a third person is inferred. Hence, they developed the Appreciation Scale, a multidimensional 57-item questionnaire, which measures eight dimensions of gratitude: appreciation of people, possessions, the present moment, rituals, feeling of awe, social comparisons, existential concerns, and behavior that expresses gratitude.

In addition to the instruments already mentioned, Morgan et al. (2017) introduced the Multi-Component Gratitude Measure (MCGM), which consists of 43 items and measures trait gratitude and four components: conceptions of gratitude, grateful emotions, attitudes toward gratitude, and gratitude related behaviors. Hlava, Elfers, and Offringa (2014) developed the Transpersonal Gratitude Scale (TGS) adding a transpersonal and spiritual dimension to the construct. The scale is comprised of 16 items and four subscales: expression of gratitude, value of gratitude, transcendent gratitude, and spiritual connection.

Another measure is the Gratitude Questionnaire – 20 items (Bernabé-Valero et al., 2014), which includes various types of gratitude, takes into consideration the different basic processes of gratitude, and assesses the cognitive, evaluative, emotional, and interpersonal processes of the construct. A self-report scale that measures gratitude as an emotion, mood, or disposition depending on the timeframe specified in the instructions is the Gratitude Adjective Checklist (GAC). It consists of 3 items that express favorable, neutral, and unfavorable affirmations toward gratitude. The GAC (McCullough et al., 2002) is the sum of three adjectives: gratefulness, thankfulness, and appreciativeness (McCullough et al., 2002; Froh et al., 2007).

Martini et al. (2016) developed the Perceived Gratitude Scale (9 items), which measures the perception of gratitude of users to socio-sanitary operators. Youssef-Morgan et al. (2022) evaluated a 10-item multidimensional measure, which was based on the approach employed by Luthans et al. (2007), namely the Work Gratitude Scale (WGS). It encompasses recognized conative (intentional), cognitive, affective, and social aspects of gratitude and measures overall work-related gratitude. The State Gratitude Scale (Spence et al., 2014) is a 5-item unidimensional scale, that assesses the actual experience of gratitude, conceptualized as a transitory state that is discrete and episodic in nature. The Functionality Appreciation Scale (Alleva et al., 2017) and the Body Appreciation Scale-2 (Tylka, 2013) assess the appreciation for one's body, while the 6-item Christian Gratitude Scale (CGS) is developed to assess gratitude to God among Christian populations, operationalized from within the Christian tradition (Knabb et al., 2021).

The Gratitude, Appreciation, and Resentment Test (Watkins et al., 2003) is a 44-item self-report measure of dispositional gratitude and the S-GRAT (or GRAT-16) is its short-form (Thomas & Watkins, 2003). As proposed by Watkins et al. (2003), gratitude reflects distinct dimensions and it does not manifest itself as a singular construct, but as independent yet related forms of gratitude (Diessner & Lewis, 2007; Watkins et al., 2003). They also suggested that there are three characteristics within a grateful person: the lack of a sense of deprivation, the tendency to appreciate simple pleasures, and the tendency to recognize the role of others in their well-being and express that gratitude. The GRAT was developed based on this framework (Locklear et al., 2022; Watkins et al., 2003). The S-GRAT consists of 16 items, and according to Thomas and Watkins' exploratory factor analysis (EFA), is a multidimensional measure that assesses 3 factors: (a) Lack of a Sense of Deprivation (LOSD; 6 items), (b) Simple Appreciation (SA; 6 items), and (c) Appreciation for Others (AO; 4 items).

The present study

The present study aimed to provide a comprehensive assessment of trait gratitude in the Greek population by adapting one of the most widespread scales in the field and testing its validity. Research on gratitude in the Greek population is surprisingly limited. Best of our knowledge, only three studies have been conducted in Greece (Michailidis, 2021; Michailidis & Maridaki-Kassotaki, 2020; Papadopoulou et al., 2017). Two of them concern students and the other one concerns retired people. In all cases, dispositional gratitude was measured using the Gratitude Questionnaire (GQ-6) (McCullough et al., 2002). While feelings of gratitude are crucial elements of the concept of gratitude, they are not the only dimension. Another suggested component is behavior, e.g., expressing gratitude for the benevolence of others (Watkins et al., 2003). Behavior is an element that is absent from the GQ-6 (Morgan et al., 2017) construct, but it is present in the Short Gratitude, Resentment and Appreciation Test (S-GRAT).

The S-GRAT is a short and well-cited measure to assess gratitude. It has been used by previous researchers in both Western and non-Western contexts and has generated important insights into the positive effects of gratitude experiences (Oğuz-Duran, 2017; Fabio, 2016; Garg et al., 2021; Jans-Beken et al., 2015; Tomaszek & Lasota, 2018; Palazzeschi et al., 2022; Tran et al., 2022). The GRAT and its short form have been used in related research with various samples worldwide, such as adults (Fabio, 2016), workers (Palazzeschi et al., 2022), college

students (Garg et al., 2021; Lin & Huang, 2016; Oğuz-Duran, 2017) and adolescents (Tran et al., 2022), and have proved to have very good psychometric results.

Regarding reliability, results indicate that internal consistency of the GRAT and the S-GRAT is at good levels ($\alpha = >.82$) (Jans-Beken et al., 2015; Lin & Huang, 2016; Oğuz-Duran, 2017; Tomaszek & Lasota, 2018). Validity results showed that both the GRAT and the S-GRAT are associated in the expected direction with the Satisfaction With Life Scale (Jans-Beken et al., 2015; Tomaszek & Lasota, 2018 ; Oğuz-Duran, 2017; Tran et al., 2022), the Flourishing Scale (Fabio, 2016), the Positive and Negative Affect Scale (Palazzeschi et al., 2022; Jans-Beken et al., 2015; Oğuz-Duran, 2017), the Meaningful Life Measure (Fabio, 2016; Tomaszek & Lasota, 2018) the Authenticity Scale (Fabio, 2016), the Transpersonal Gratitude Scale, the Spiritual well-being scale and the Kessler Psychological Distress Scale (Garg et al., 2021), the Gratitude Questionnaire (Jans-Beken et al., 2015; Oğuz-Duran, 2017; Tran et al., 2022), the Resilience Measurement Scale - SPP-25 and the Questionnaire of Cognitive and Affective Empathy (Lasota et al., 2022; Tomaszek & Lasota, 2018), the General Self-Esteem Scale (GSE) and the Altruism Scale (Tomaszek & Lasota, 2018), the Ko Depression Inventory and the Measure of subjective well-being (Lin & Huang, 2016). These findings seem to suggest that gratitude is a universal feeling, in which noticing and receiving something valuable causes feelings of appreciation for the positive in the world. Furthermore, these findings also suggest that the benefits of gratitude may have an impact both on Western individualistic societies but also on Eastern collectivistic societies (Tran et al., 2022).

Aims and hypothesis

Given the lack of instruments of gratitude in the Greek context, which is a key impediment in the endeavor to conduct studies, the adaptation and validation of such instruments will enrich the discussion on the grateful disposition and help researchers to choose the most appropriate scale, according to the purpose of the study.

The aim of the present study was twofold. Firstly, it aimed to examine the reliability and factor structure of the Greek version of the Short Gratitude, Resentment and Appreciation Test (S-GRAT) and test the convergent and incremental validity through a psychometric evaluation of the S-GRAT. Secondly, the study aimed to examine the relationship between the S-GRAT score and demographic variables.

According to the existing studies internationally, first, it was hypothesized that the S-GRAT would demonstrate satisfactory internal consistency and that the three-factor model would be confirmed consistently with the original structure. Second, it was predicted that the S-GRAT would correlate significantly with the Big Five dimensions of personality, and would be positively and significantly correlated to life satisfaction, happiness and gratitude (using the Gratitude Questionnaire GQ-6). Thirdly, it was predicted that the S-GRAT score would show significant correlations with demographic variables such as gender and age.

Methods

Participants

Fifty individuals (N=50) from the general population, as a convenience-independent sample, participated in a test-retest study. Subsequently, a convenience sample of six hundred eighty-one (N=681) adults from the general population participated in the main study. Participants of the latter sample were 44.6% male and 55.4 % female, and their mean age was 31.4 years ($SD = 10.5$). Most participants were single (57.3%). Undergraduate students were 35.2% and 34.2% were university graduates. Regarding work status, 54.4% of participants were private employees and state servants, while 25% were unemployed (Table 1).

Translation process

The Greek version of the Short Gratitude, Resentment, and Appreciation Test (S-GRAT-Gr) was translated based on the suggestion of Gudmundsson (2009) and the WHO guidelines for translation.

Forward Translation. First, two bilingual translators (T1 and T2), who were familiar with English-speaking culture, had a different profile and background, and whose mother tongue was Greek language, translated the questionnaire into Greek. Translator 1 was a psychologist. She had experience in research and tests, had excellent English skills, was familiar with both cultures and was aware of the concepts explored in the questionnaire being translated. Translator 2 was a professional English translator. Each translated the questionnaire independently of the other and they provided two translations. A reconciliation meeting was then held to reconcile the two independent forward versions. After comparing the two versions and evaluating them in terms of conceptual equivalence, comprehensibility, and linguistic clarity compared to the English questionnaire, a common version was produced.

Expert Panel. A committee of six bilingual members (the translators T1 and T2, a psychologist, a social worker, a sociologist, and a university professor) reviewed the translated version and the original questionnaire. The aim was to ensure idiomatic, semantic, and conceptual equivalence between the versions, and to eliminate any discrepancies between the translated and original versions.

Back Translation. The next step was a backward translation of the initial Greek version by an independent translator whose native language was English and who did not know the original English version. Subsequently, the translated form was sent to the developer of the S-GRAT-Gr for his recommendations.

Pre-Testing Version. the prefinal version was used and tested on a general adult population ($N = 15$) that differed in sociodemographic characteristics. Cognitive interviewing (CI) was used as a key qualitative method for pretesting and evaluating the questions to determine if the true meaning of the question, as intended by the researchers, was conveyed to the respondents and if questions were understandable (Peterson et al., 2017). Cognitive interviewing was conducted using the think-aloud method to uncover participant difficulties and offer suggestions for clarity, understanding, and relevance of the prefinal version (Dietrich & Ehrlenspiel, 2010; Willis, 2005). All participants were asked to report on their experiences and impressions during the completion process.

Final Version. All evidence, assessments, and recommendations from the above phases were used to refine the prefinal Greek version, and necessary modifications were made. The final version of the Greek S-GRAT (S-GRAT-Gr) is presented in the Appendix A.

Research instruments

The Short Gratitude, Resentment, and Appreciation Test (S-GRAT-Gr). The S-GRAT is a 9-point Likert scale, which ranges from strongly disagree (1) to strongly agree (9). Five negatively worded items are reverse coded (3, 6, 10, 11 & 15). The total score ranges from 16 to 144, with high scores indicating higher levels of grateful disposition. Cronbach's alpha of reliability has been calculated as .92 for the original scale (Thomas & Watkins, 2003) and .88 for the present study. An example item of the LOSD factor is "Life has been good to me", of the SP factor "Every Fall I really enjoy watching the leaves change colors", and of the SA factor "I feel deeply appreciative for the things others have done for me in my life" (Watkins et al., 2003).

Gratitude Questionnaire (GQ-6). The Gratitude Questionnaire (GQ-6), developed by McCullough et al. (2002), is a brief self-report measure of the tendency to recognize, respond, and experience gratitude in daily life. The scale consists of six items, two of which are reverse-coded. Participants respond on a 7-point Likert scale (1= "strongly disagree", 7= "strongly agree"), that can be completed in less than five minutes. Scores range from 6-42, with high scores indicating higher level of dispositional gratitude. The GQ-6 has good internal consistency, with

alphas ranging from .76 to .84 (McCullough et al., 2002). In the present study, Cronbach's alpha was .73. The GQ-6 was adapted and validated for use in the Greek population by Michailidis and Maridaki-Kassotaki (2020).

Satisfaction with life scale. The Satisfaction with Life Scale is a short 5-item instrument developed by Diener et al. (1985) designed to measure global cognitive assessments of satisfaction with one's life. The scale does not assess satisfaction with specific life domains but allows individuals to integrate and weigh these domains in whatever way they choose. Responses are classified on a 7-point Likert scale, with 1 representing “*strongly disagree*” and 7 representing “*strongly agree*”. This results in a total score between 5 and 35 units. Higher scores indicate greater life satisfaction. The Satisfaction with Life was adapted and validated for use in the Greek population by Lyrakos et al. (2013a). The reliability indicator established for the Greek adaptation of the scale and in the present study was high enough ($\alpha=.83$ and $.85$, respectively).

The Subjective Happiness Scale. The SHS is a 4-item scale of global subjective happiness (Lyubomirsky & Lepper, 1999). It consists of 4 items, two of which ask respondents to characterize themselves using both absolute ratings and ratings relative to peers, while the other two items offer brief descriptions of happy and unhappy people and ask respondents to what extent each characterization describes them. These items can be answered on a 7-point scale, ranging from 1 (*not very happy*) to 7 (*very happy*). Items 1, 2, and 3 are positive items and item 4 is reverse scored. A higher score on the SHS indicates higher subjective happiness. It was adapted and validated for use in the Greek population by Lyrakos et al. (2013). According to the results of the validation study and the present study, coefficient alpha was $.75$ and $.77$, respectively.

International Personality Item Pool (IPIP). The IPIP-Big 5 (Goldberg et al., 2006), which replaced the NEO PI-R, is a 50-item self-report personality test measuring the Big Five personality traits, consisting of 10 items for each of the Big-Five personality factors: Extraversion (E), Agreeableness (A), Conscientiousness (C), Emotional Stability (ES) and Intellect (I). Participants rate themselves on a 5-point Likert scale from 1 (*very inaccurate*) to 5 (*very accurate*), depending on how accurately each statement describes them. It was adapted and validated for the Greek population by Ypofanti et al. (2015). Cronbach's alpha coefficient for the total score of the IPIP questionnaire in the validation study was $.88$ and in the present study was $.89$.

Procedure

Both studies were conducted in 2019 in the Peloponnese Region, which is situated in the southern part of mainland Greece. The data of the test-retest study ($N=50$) were collected in person. The data of the main study ($N=681$) were collected in person and online through social media and e-mails (using Google Forms). Researchers informed participants of the general purposes and benefits of the study and asked them to complete an informed consent form. Participation was voluntary, and confidentiality and anonymity were ensured. The study was approved by the Research Ethics Committee of the Health Science School, University of Peloponnese, and was in accordance with the Helsinki Declaration of 1975, as revised in 1983.

Data analysis plan

Internal consistency was evaluated through Cronbach's alpha and McDonald Omega coefficient (ω) as a measure of reliability. Test-retest reliability coefficient was calculated through Spearman's correlation coefficient and Intraclass correlation coefficient (ICC, Portney & Watkins, 2009), while the Kolmogorov test showed that the variables were not normally distributed ($p<.0001$). Wilcoxon test was used to calculate effect size.

Since the purpose of this study was to validate and investigate the structural validity and reliability of the instrument, an EFA was conducted to determine the components of the scale using principal axis factoring analysis (FCA) with varimax rotation on the 16-item scale. A Parallel Analysis (PA) was conducted on the items. The simulation was executed with 100 parallel datasets based on permutations of the original raw data set, with

the criterion set at the 95th percentile (Hair et al., 2019; Lim & Jahng, 2019; Watkins, 2018). According to the suggestions of researchers and test developers, Varimax rotation is the method of choice in the field of personality assessment (Cheung et al., 2008; Henson & Roberts, 2006). Bartlett's Test of Sphericity (significant at $p < .001$) and Kaiser-Meyer-Olkin (KMO) ($>.50$) were applied to determine sample adequacy for factor analysis, and eigenvalues >1 , communalities and factor loadings $>.4$ were examined to interpret factors (Child, 2006; Hair et al., 2019; Watkins, 2018).

Statistical methods of Skewness and Kurtosis to check normality of the data were applied. Confirmatory Factor Analysis (CFA) was applied through the maximum likelihood estimation method to confirm the goodness fit, the validity and the reliability of the measurement model. As part of the analysis, factor loadings for each item were assessed. Model-fit measures used to assess the model's overall goodness of fit were Chi-Square (χ^2), $\chi^2/\text{degrees of freedom}$ (χ^2/df), (Root Mean Square Error of Approximation (RMSEA), Comparative Fit Index (CFI), Goodness of fit index (GFI), Standardized Root Mean Squared Residual (SRMR), Parsimonious Normed Fit Index and Parsimony Comparative Fit Index (PNFI) (Harrington, 2009; Tabachnick & Fidell, 2013). Regarding reliability, Cronbach's α was calculated as a measure of the internal consistency of scale and factors (Nunnally & Bernstein, 1994). Hu and Bentler (1999), Brown (2015), and Tabachnick and Fidell (2013) suggest: $\chi^2/\text{df} < 2$, $\text{RMSEA} \leq .06$, $\text{SRMR} \leq .08$, $\text{CFI} \geq .95$ και $\text{GFI} \geq .95$, while others disagree. Kline (2010) recommends $\text{CFI} > .90$ and Bentler (1990) suggests $\text{CFI} > .90 - .95$ as a perfect level. Marsh & Hocevar (1985) suggests the ratio $\chi^2/\text{df} < 5$ and Meyers et al. (2006) recommend $\text{GFI} \geq .90$, $\text{RMSEA} \leq .08$, $\text{PNFI} > .50$ and $\text{PCFI} > .50$. The SRMR cutoff value recommended by Hu and Bentler (1999) for a good fit model is equal to or less than .08.

Correlation analyses were examined using Pearson coefficient r and regression analysis was performed for convergent and divergent validity. In order to estimate effect size further from R^2 , Cohen's f was calculated. It has been suggested by Cohen (1988) that $f = .01$ can be considered a small size effect, .25 a medium, and $> .40$ a large size effect. The first regression was performed with the Satisfaction with Life as the criterion. The Big Five personality dimensions were entered as Block 1, the GQ-6 score was added to the equation (Block 2) and the Global S-GRAT-Gr score was entered as the third block. To further investigate incremental validity, the analyses were rerun with the three S-GRAT-Gr factors entered as the last block instead of the global S-GRAT-Gr. The second regression was performed following the same procedure with the Subjective Happiness Scale as the criterion. Statistical analyses were performed using SPSS v.26 and SPSS AMOS v.26. and all tests were considered statistically significant at $p < .05$.

Results

Demographic characteristics of the main study participants ($N = 681$) and bivariate analysis for the association between socio-demographic variables and gratitude score are presented in Table 1, reporting each included variable and p values.

Internal consistency and test – retest reliability

The analysis demonstrated that the results were consistent and stable. In the first completion, internal consistency of the S-GRAT-Gr was $\alpha = .887$ and McDonald $\omega = .879$, and in the second completion Cronbach's alpha and McDonald ω was .935 and .931 ($N=50$), respectively. Spearman's correlation coefficient and intraclass correlation (ICC) revealed a high test-retest correlation at the total score of S-GRAT-Gr (Spearman's $r = .864$; $p < .001$ and $\text{ICC} = .948$; $p < .001$). The mean total score after the first completion was 118.11 (± 15.59), whereas after the second it was 117.86 (± 18.91). The difference between the mean scores was not statistically significant ($p = .814$) and the effect size therefore was quite small ($r = .06$).

Table 1*Demographic variables and their relationship with gratitude*

Gender			Age	Marital Status		Educational Level			Work Status			
	N	Mean (SD)	Mean (SD)		N	Mean (SD)		N	Mean (SD)		N	Mean (SD)
Male	304	107,24±17,90	31.46±10.52 ¹	Single	309	109.28±17.79	Higher secondary education	63	108.03±17.46	Unemployed	170	108.39±17.33
Female	377	114,85±16,57		Married	208	114.42±16.63	Undergraduate student	240	108.55±18.12	State employee	136	113.70±17.38

Note. ¹: Mann-Whitney U, ²: Kruskal-Wallis Test, SD: standard deviation, *p<.05; **p<.001.

Structural validity and reliability

An EFA approach was performed in a randomly selected sample (subsample from total sample, $N = 300$) to explore the construct validity of the S-GRAT-Gr (Table 2) and a Parallel Analysis (PA) was conducted on the items. First, the KMO measure and Bartlett's test for sphericity were used to determine the factor structure of the instrument. The KMO and Bartlett's test of sphericity for the total sample yielded a measure of .866, $p < .001$ [$X^2_{(300)} = 2279.28$, $df = 120$, $p < .01$]. Anti-image correlation values for all items were $> .721$, which is well above the acceptable limit of .50. A Principal Axis Factoring Analysis with Varimax rotation yielded the three-factor solution and Parallel analysis estimating this solution was appropriate. Factor loadings for the 16 items ranged from .55 to .82. Eigenvalues were greater than 1 and communalities of the items in the three-factor solution were all greater than .4. Factor 1 and factor 2 contained 6 items each and accounted for 35.8% and 14.8% of the variance, respectively. Factor 3 contained 4 items and accounted for 11.2% of the variance. The three-factor solution explained 61.908% of the total variance in the sample, which is considered acceptable (Zikmund et al., 2010).

Before examining Confirmatory factor analysis, the normal distribution of the data was assessed. Skewness (the range was between -2.2 to -.43) and kurtosis (the range was between -.22 to +6.07) indicated that data was normally distributed (Field, 2013; Kline, 2015; Tabachnick & Fidell, 2013). Confirmatory factor analysis (CFA) was performed ($N = 681$) to examine the dimensionality of the S-GRAT-Gr, a three-factor model with 16 items, and to determine whether the newly collected data adequately fit the original structure. The three-factor model showed good fit to the data: $X^2_{(681)} = 486.86$, $p < .001$, $df = 101$, $\chi^2/df = 4.82$ RMSEA = .075 (90% CI of RMSEA = .07-.08), GFI = .92, CFI = .92, SRMR = .057, PNFI = .76 και PCFI = .79 and all values were within their common acceptance levels. The CFA results indicate that the model has acceptable fit indices, and they confirmed the three-factor structure of the original model over a Greek sample. The factor loadings of the scale ranged from .54 to .86. Hence, results showed high error covariances between variables e4 (.54) and e7 (.66), and an error covariance path was added to the model to improve fit. After combining these two items, which are theoretically related, the model fit indices were re-examined. The results showed better fit: $X^2_{(681)} = 302.9$, $p < .001$, $df = 100$, $\chi^2/df = 3.03$ RMSEA = .055 (90% CI of RMSEA = .05 - .06), GFI = .95, CFI = .96, SRMR = .049, PNFI = .79 και PCFI = .80 (Figure 1).

Cronbach's alpha of internal consistency (Table 3) was calculated as .87 for the Lack of a Sense of Deprivation factor, .85 for the Simple Appreciation factor, .86 for the Appreciation of Others factor and .88 for the total score of the GRAT-S, indicating good reliability, greater than the acceptable limit of .70 (Nunnally & Bernstein, 1994). McDonald omega was calculated as .87, .84, .85 and .87 respectively. Furthermore, Cohen's f was performed, and it is presented in Table 3.

Zero order correlations

Bivariate (zero-order) correlations between the key variables of the study are presented in Table 3. Regarding the personality dimensions, the S-GRAT-Gr showed a moderate positive correlation with Agreeableness ($r = .46$, $p = .01$) and positive, weaker but significant correlations with Intellect ($r = .27$, $p = .01$), Extraversion ($r = .25$, $p = .01$), Emotional Stability ($r = .22$, $p = .01$) and Conscientiousness ($r = .18$, $p = .01$). The scores of the LOSD and SA subscales also correlated with the five personality dimensions (Table 2), whereas the score of AO correlated positively with three personality traits ($r = .17$, .38 and .15; $p = .01$, for Intellect, Agreeableness and Extraversion, respectively). In addition, the total score of the S-GRAT-Gr and the score of the AO subscale presented strong positive correlations with the GQ-6 score ($r = .73$ and .64; $p = .01$, respectively), followed by the scores of LOSD ($r = .50$, $p = .01$) and SA ($r = .56$, $p = .01$). With respect to the criteria, the total S-GRAT-Gr and the LOSD subscale scores presented moderate positive correlations with Happiness ($r = .41$ and .41; $p = .01$, respectively) and Life Satisfaction ($r = .52$ and .50; $p = .01$, respectively), whereas the SA and AO scores presented weaker but still significant positive correlations with both variables (Table 3).

Incremental validity

Table 4 provides the effect size and the statistical indices for each block of the two regression models. The Big Five personality dimensions were entered as block 1, the GQ-6 score was added to the equation (block 2) and the global S-GRAT-Gr score was entered as the third block. To further investigate the incremental validity, the analyses were rerun with the three S-GRAT-Gr factors entered as the last block instead of the global S-GRAT-Gr. To develop general estimates of the incremental validity magnitude of the S-GRAT-Gr score, we also evaluated the size of the validity increment based on semi partial r (Hunsley and Meyer, 2003).

The first regression was performed with The Satisfaction with Life Scale as the criterion. At step 1, the Big Five personality dimensions accounted for variability in the dependent variable. More specifically, Conscientiousness ($\beta = .09$; $t = 2.23$; $sr = .08$; $p < .05$), Emotional Stability ($\beta = .16$; $t = 4.16$; $sr = .15$; $p < .001$), Agreeableness ($\beta = .08$, $t = 2.05$, $sr = .07$; $p < .05$) and Extraversion ($\beta = .15$, $t = 3.53$; $sr = .13$; $p < .001$) were individually significant predictors. The GQ-6 score was added to the equation (block 2) and the model gained additional explanatory power ($\beta = .36$; $t = 9.21$; $sr = .32$; $p < 0.001$). The global S-GRAT-Gr score was entered as the third block, causing a significant incremental contribution, with the global S-GRAT-Gr being a significant predictor ($\beta = .47$, $t = 9.67$; $sr = .31$; $p < .001$). When we rerun the analysis entering the three S-GRAT-Gr factors as the last block instead of the global S-GRAT-Gr, two of the three factors resulted in a significant contribution: LOSD ($\beta = .35$; $t = 9.22$; $sr = .29$; $p < .001$) and AO ($\beta = .20$; $t = 4.70$; $sr = .15$; $p < .001$).

The second regression was performed with The Subjective Happiness Scale as the criterion. The Big Five dimensions (block 1) accounted for variability in the dependent variable with Emotional Stability ($\beta = .23$; $t = 6.25$; $sr = .22$; $p < .001$) and Extraversion ($\beta = .20$, $t = 4.73$; $sr = .17$ $p < .001$) being individually significant predictors. The GQ-6 score was entered as block 2 and the model gained additional explanatory power ($\beta = .31$; $t = 7.85$; $sr = .27$; $p < .001$). The global S-GRAT-Gr score was entered as the third block, causing a significant incremental contribution, with the global S-GRAT-Gr being a significant predictor ($\beta = .28$, $t = 5.45$; $sr = .18$; $p < .001$). Analyses were rerun with the three S-GRAT-Gr factors entered as the final block instead of the global S-GRAT-Gr. This change resulted in a significant model, with a significant contribution for the LOSD factor ($\beta = .24$; $t = 5.90$; $sr = .20$ $p < .001$). No significant contributions were found for the SA or the AO factor.

Table 4. Hierarchical Regression Analyses With the IPIP-Big Five (Step 1), the GQ-6 (Step 2), and Either the Global S-GRAT-Gr (Step 3a), or the S-GRAT-Gr Factors (Step 3b)

Criterion	Satisfaction with Life Scale			Subjective Happiness Scale		
Step 1	$F(5,675)=17.20^{***}$ $R^2_{adj} = .11$, Cohen's $f = .35$			$F(5,675)=22.31^{***}$ $R^2_{adj} = .14$, Cohen's $f = .40$

*Note. The variables entered at Steps 1 and 2 were the same for each model. Step 3 was performed twice for each criterion, the first time with the global S-GRAT-Gr score as a predictor (Step 3a) and the second time with the four S-GRAT-Gr factor scores as predictors (Step 3b). *S-GRAT-Gr*: The Greek Short Gratitude, Resentment, and Appreciation Test. *GQ-6*: Gratitude Questionnaire.

R^2_{adj} : adjusted R^2 , ΔR^2_{adj} : change in adjusted R^2 , sr : semipartial r , β : regression coefficient.

** $p < .05$; *** $p < .001$.

Discussion

The present study was the first attempt to validate one of the most widely used measures of dispositional gratitude, the Short Gratitude Resentment and Appreciation Test (S-GRAT-Gr), in the Greek context.

Reliability and construct validity of S-GRAT-Gr

In terms of reliability, internal consistency for the total score and subscales of the S-GRAT-Gr was good and test – retest reliability was high. The EFA revealed a three-factor solution that explained the total acceptable (Zikmund et al., 2010) sample variance of 61.908 %. Results from CFA showed that the model had acceptable fit indices and confirmed the three-factor structure of the original model (Watkins et al., 2003) for a Greek sample. However, a high error covariance was detected between variables e4 and e7, so an error covariance path was added to improve the model. A possible explanation for the error revealed could be that the relationship between item 4 and item 7 is due to the fact that they belong to the same factor (Simple Appreciation). This is evident in the wording of the items: item 4 (Oftentimes I have been overwhelmed at the beauty of nature) and item 7 (Every Fall I really enjoy watching the leaves change colors). According to Watkins et al. (2003), grateful persons appreciate simple pleasures: “*Simple pleasures refer to those pleasures in life that are readily available to most people*” (p. 432). Consequently, these items are related in content. Despite the similarity, it was decided to include both items because item 4 covers the intensity of pleasure compared to 7.

Convergent validity of S-GRAT-Gr

With respect to convergent validity, the results showed that the total score of the S-GRAT-Gr and the scores of its subscales were moderately to strongly positively correlated with the GQ-6 score. The results are consistent with previous research findings in adult samples (Froh et al., 2011; Jans-Beken et al., 2015; Tran et al., 2022) and indicate that both scales assess the conceptualization of grateful disposition. Moreover, nomological network analysis showed that both the total score of the S-GRAT-Gr and the score of the subscales presented positive correlations with life satisfaction and happiness. These results suggest that a grateful person, who feels abundance in life, appreciation for the common pleasure of everyday aspects as well as for others’ contributions to his or her well-being, evaluates his or her life circumstances to a greater extent and feels happier than people who do not reflect upon what they are grateful for. Relevant studies have confirmed this relationship (Froh et al., 2011; Garg & Mehak, 2021; Jans-Beken et al., 2015; Lin & Huang, 2015; Palazzeschi et al., 2022; Thomas & Watkins, 2003), in which positive emotions such as gratitude seemed to determine subjective happiness and satisfaction with life. Fredricksons’ (1998, 2001) broaden-and-build theory states that positive emotions have transformative power because they broaden people's momentary thought–action repertoires by having a great impact on habitual modes of thinking, cognition, and action and build enduring personal growth by promoting physical, intellectual, and social resources. In other words, positive emotions fuel human flourishing (Fredrickson, 2001). Fredrickson (2004) also highlights that gratitude can be a representative positive emotion that fundamentally changes the functioning of human brain, by fostering the broadening and building of structural functions (Fredrickson, 2004). Additionally, gratitude has a crucial regulatory effect on negative emotions (Lodice et al., 2021; Manita et al., 2020; McCullough et al., 2002), which in turn promotes life satisfaction and happiness.

The results of the study also highlight the cross-cultural consistency of the relationship between basic personality taxonomies and dispositional gratitude. As expected, the strongest correlation was observed between the total score of the S-GRAT-Gr and Agreeableness, indicating that one’s tendency to perceive and appreciate positive aspects of life is linked with pro-social traits, such as forgiveness, trust, generosity,

kindness, sympathy, and leniency. Dispositional gratitude also showed positive correlations with the other four personality traits. Grateful people are more likely to be curious and creative (Intellect), sociable and active (Extraversion), calm and relaxed (Emotional Stability), organized and reliable (Conscientiousness). These findings are consistent with other studies (Szcześniak et al., 2020; Wood et al., 2010; 2009; 2008) and support the relationship between personality traits and dispositional gratitude.

Incremental validity of S-GRAT-Gr

To confirm the usefulness of the S-GRAT-Gr score for personality assessment, we tested its unique contribution to criteria beyond existing tests that serve a theoretically similar construct. More specifically, we addressed the incremental validity of the S-GRAT-Gr score by conducting a three-step hierarchical regression for each criterion in the study. We sought to answer whether the S-GRAT-Gr score adds a new and unique explanation of variance in the SHS and the SWLS that is not accounted by the IPIP-Big 5 and the GQ-6. The later constructs, because of their theoretical and empirical relationship to the former, constitute a major hurdle beyond which the newly established scale should demonstrate incremental validity. To develop general estimates of the incremental validity magnitude of the S-GRAT-Gr scores, we also evaluated the size of the validity increment that is based on the semi partial r (Hunsley & Meyer, 2003).

In all cases, the global S-GRAT-Gr score or the scores of the S-GRAT-Gr factors were entered as the third block. The global S-GRAT-Gr score demonstrated a statistically significant increase in predicting Life Satisfaction (10%) and Happiness (3%) beyond the previously entered variables, answering the question of the weak utility of the scale. According to Hunsley and Meyer (2003), a semi partial (or incremental) r of .15 to .20 at the third step of the regression analysis indicates a reasonable contribution to the existing equation. The semi partial r was greater than .15 for both criteria, demonstrating the significance of this increase. The S-GRAT-Gr score had a unique impact on Life Satisfaction and Happiness beyond the basic taxonomies of personality and also beyond the GQ-6. The latter further highlights the potential theoretical contribution of the S-GRAT-Gr score, as both scales assess dispositional gratitude. The results are consistent with the research findings of Jans-Beken et al. (2015) in the Dutch context and suggest that the S-GRAT score refers to a different conceptualization of grateful disposition that has a major impact on aspects of everyday life. Nevertheless, a non-significant effect was found at the regression level of the analysis of the Simple Appreciation (SA) factor. The incremental evidence for the validity of the Lack of a Sense of Deprivation (LOSD) factor score is replicated by emerging evidence (Hammer & Brenner, 2017; Jans-Beken et al., 2015), whereas the findings of the incremental contributions of Simple Appreciation (SA) and Appreciation of Others (AO) are controversial (Hammer & Brenner, 2017; Jans-Beken et al., 2015) and still in their “infancy”. Consequently, further research should attempt to demonstrate the incremental predictive power of the specific factors Simple Appreciation (SA) and Appreciation of Others (AO) in the context of other criterion variables.

Gratitude and demographic variables

With respect to the existing literature, there is very little research on the association between gratitude and socio-demographics.

Gender. There is a small number of published studies examining how gender relates to gratitude. The present study revealed significant gender differences in gratitude, with women scoring higher than men. Regarding the Greek cultural context, this finding is consistent with previous studies which indicate that women are more likely to experience, express and embrace gratitude (Gordon et al., 2011; Kashdan et al., 2006; Yue et al., 2017). It is suggested that men are less practiced at expressing emotions in the context of socializing and less willing to express softer emotions such as gratitude (Kashdan et al., 2006). On the other hand, women

are more aware of their emotions, and they experience and express them more intensively and frequently than men (Barrett et al., 2000; Ciarrochi et al., 2005; Naito et al., 2005; Simon & Nath, 2004). Furthermore, gender differences in emotions could partially be the result of stereotypical gender roles. According to the traditional masculinity and femininity roles, women are more likely to be caring and pleasing while men are required to be strong and brave (Fischer et al., 2004; Plant et al., 2000). Another hypothesis is that biological factors influence emotional differences, such as the different hormonal and brain compositions, according to which women are more reactive when feeling positive emotions than men and are better in perceiving emotions (Brebner, 2003; Whittle et al., 2017).

Age. Age was positively correlated with global trait gratitude. In Greece, age seems to have an impact on individuals' gratitude, as they become more grateful as they are getting older. Studies on the association between chronological age and trait gratitude have found both positive and null associations (Kern et al., 2016; Kashdan et al., 2006; Wood et al., 2008). The Socioemotional Selectivity Theory could provide an explanation. As people age, they become increasingly aware that time is limited and this perception of a finite time may lead them to prioritize meaningful events and to greater gratitude (Carstensen, 2006; Carstensen et al., 1999). Another proposed explanation could be that older adults tend to provide more positive evaluations of their lives and emotional states (Isaacowitz et al., 2006) and invest more in social relationships that afford greater well-being (Carstensen & Mikels, 2005; Reed & Carstensen, 2012).

Educational level. As far as the educational level is concerned, it was observed that education was associated with individuals' gratitude. Specifically, participants in the present study who reported higher education level reported higher levels of gratitude as well. These findings might reflect the fact that education can have a significant positive impact on personal well-being and consequently on gratitude. It has been found that higher levels of education lead to higher levels of happiness, well-being and life satisfaction (Cuñado & de Gracia, 2012; Nikolaev, 2018). Highly educated individuals tend to appreciate family, friends, and relatives and they spend more time with them; this has positive effect on well-being (Nikolaev, 2018), which is strongly related to gratitude (Wood et al., 2010).

Marital status. Participants who were married or cohabiting with their partners scored higher on global trait gratitude compared to the single and divorced ones. This finding may indicate that partnership in Greece contributes to grateful feelings. It is well established that married individuals report greater well-being compared to single or divorced (Wadsworth, 2016). Studies suggested that cohabitation is associated with well-being the same way as marriage (Rapp & Stauder, 2020). However, it should be noted that only a few participants reported cohabitation in the present study (n=44), which does not allow to define a conclusion.

Summarizing, the evidenced strong internal consistency and validity of the Greek version of the short Gratitude Resentment and Appreciation Test allows its use for conducting psychological and interdisciplinary research work. The S-GRAT-Gr may further be used in the Greek context to measure dispositional gratitude.

In the psychological realm, there is an increased interest in the study of gratitude. Research on gratitude in Greece, a country characterized by higher collectivistic values (Kafetsios et al., 2018), is still scarce. There is increasing evidence for cross-cultural differences in positive psychological interventions (Ng & Lim, 2019) and the function of gratitude in collectivistic cultures, in particular (Titova et al., 2017). The present study contributes to the study of gratitude, while it is one of the first to measure gratitude using a short questionnaire with sufficient psychometric properties. This allows the opening of new research avenues and intervention perspectives centering on gratitude as a variable, which is associated with individual's well-being. An advantage of the S-GRAT-Gr over other instruments for measuring gratitude is its ability to provide a more comprehensive assessment with its three dimensions and total score (Watkins, 2003).

Despite the sample size, it is important to note that the main limitation to generalizing these results is that participants in the present study were not randomly selected, which have led to an unbalanced sample in terms of participants' gender, marital status, and education. Therefore, a guarded interpretation is recommended when reading the findings. Future studies should include representative samples in terms of age, gender, education level, work status, urban or rural residence, and investigate whether the present results are stable across groups. Regarding the use of self-report method for data collection, a potential limitation is desirability bias that may have affected the results. Undoubtedly, there is much retain to be learned about gratitude in the Greek context and its relationship with different personal and social variables.

There are several reasons why gratitude could be an interesting and promising construct to explore further. In the positive psychology framework, gratitude is positively associated with a wide range of positive psychological outcomes, and negatively with variables such as psychological distress, depression, anxiety, envy, anger, etc. This research may provide researchers and counselors with a short tool that contributes to a general improvement of well-being and could serve as a powerful psychological buffer to enhance resilience. Especially after the recent Covid-19 pandemic, there is a pressing need for examining the psychological and social effects on the population and general mental health of individuals.

Appendix A

The Greek version of the short Gratitude Resentment and Appreciation Test (S-GRAT-GR)

Αριθμός ερώτησης	Ερώτηση	Διαφωνώ απόλυτα	Διαφωνώ	Διαφωνώ λίγο	Μάλλον διαφωνώ	Ούτε διαφωνώ, ούτε συμφωνώ	Μάλλον συμφωνώ	Συμφωνώ ως επί το πλείστον	Συμφωνώ	Συμφωνώ απόλυτα
1	Δεν θα βρισκόμουν στο σημείο που είμαι σήμερα χωρίς την βοήθεια πολλών ανθρώπων.									
2	Η ζωή υπήρξε καλή μαζί μου.									
3	Φαίνεται ότι τα καλά πράγματα στη ζωή μου ποτέ δεν είναι αρκετά και ποτέ δεν παίρνω αυτό που μου αναλογεί.									
4	Συχνά κατακλύζομαι από την ομορφιά της φύσης.									
5	Παρόλο που θεωρώ ότι είναι σημαντικό να νιώθω καλά με τα επιτεύγματά μου, θεωρώ εξίσου σημαντικό να θυμάμαι ότι έχουν συμβάλει κι άλλοι στην επιτυχία μου.									
6	Δεν θεωρώ ότι έχω πάρει όλα τα καλά πράγματα που μου αξίζουν στη ζωή.									
7	Κάθε φθινόπωρο απολαμβάνω πραγματικά να βλέπω τα φύλλα που αλλάζουν χρώμα.									
8	Παρόλο που κατά βάση εγώ έχω τον έλεγχο στη ζωή μου, δεν μπορώ να μην σκέφτομαι όλους αυτούς που με στήριξαν και με βοήθησαν στη διαδρομή.									
9	Θεωρώ ότι είναι σημαντικό να κάνω μια παύση από την καθημερινότητα και να εκτιμώ τις ομορφιές της ζωής.									
10	Στη ζωή μου, μου έχουν συμβεί περισσότερα άσχημα πράγματα από ότι άξιζα.									
11	Εξαιτίας των όσων έχω περάσει στη ζωή μου, πιστεύω ότι ο κόσμος μου χρωστά κάτι.									
12	Θεωρώ ότι είναι σημαντικό να κάνω συχνά μια «παύση» και να νιώθω ευλογημένος για όσα έχω.									
13	Θεωρώ ότι είναι σημαντικό να απολαμβάνεις τα απλά πράγματα στη ζωή.									
14	Νιώθω βαθιά ευγνωμοσύνη για αυτά που έχουν κάνει οι άλλοι για μένα στη ζωή μου.									
15	Για κάποιο λόγο φαίνεται ότι δεν έχω ποτέ τα πλεονεκτήματα που έχουν άλλοι.									
16	Θεωρώ ότι είναι σημαντικό να εκτιμάς την κάθε μέρα που είσαι ζωντανός.									

The following items should be reverse scored: 3, 6, 10, 11, 15

The following items form the Lack of a Sense of Deprivation (LOSD) factor: 2, 3, 6, 10, 11, 15

The following items form the Simple Appreciation (SA) factor: 4, 7, 9, 12, 13, 16

The following items form the Appreciation for Others (AO) factor: 1, 5, 8, 14

Total is from all items.

Αξιοπιστία και Εγκυρότητα της Ελληνικής Εκδοχής του Σύντομου
Τεστ Ευγνωμοσύνης, Δυσαρέσκειας και Εκτίμησης (S-GRAT-GR)

ΛΕΞΕΙΣ ΚΛΕΙΔΙΑ	ΠΕΡΙΛΗΨΗ
Ευγνωμοσύνη S-GRAT Αξιοπιστία Εγκυρότητα Προσωπικότητα Ευτυχία Ικανοποίηση από τη Ζωή	Η ευγνωμοσύνη έχει εννοιολογηθεί ως συναισθηματικό χαρακτηριστικό, διάθεση ή συναίσθημα και έχει συσχετιστεί με πολυάριθμα ευεργετικά αποτελέσματα για τα άτομα και τις κοινότητες. Το σύντομο Τεστ Ευγνωμοσύνης, Δυσαρέσκειας και Εκτίμησης (S-GRAT-Gr) αποτελεί ένα από τα πιο ευρέως χρησιμοποιούμενα εργαλεία μέτρησης της ευγνωμοσύνης ως χαρακτηριστικό, το οποίο αποτελείται από τρεις υποκλίμακες οι οποίες αξιολογούν την έλλειψη αίσθησης στέρησης, την εκτίμηση των απλών απολαύσεων και την κοινωνική εκτίμηση. Η παρούσα μελέτη εξέτασε τις ψυχομετρικές ιδιότητες της ελληνικής εκδοχής του S-GRAT. Χρησιμοποιώντας ένα δείγμα 681 και ένα μικρότερο δείγμα 50 ενηλίκων γενικού πληθυσμού, διαπιστώσαμε ότι η κλίμακα επέδειξε καλή αξιοπιστία εσωτερικής συνοχής και υψηλή αξιοπιστία δοκιμασίας – επαναδοκιμασίας. Η διερευνητική και επιβεβαιωτική ανάλυση επιβεβαίωσαν την αρχική δομή της κλίμακας τριών παραγόντων. Η συγκλίνουσα εγκυρότητα της υπό στάθμισης κλίμακας επιβεβαιώθηκε μέσω των στατιστικά σημαντικών συσχετίσεων του ολικού σκορ του S-GRAT-Gr με την Προσήνεια, την Πνευματική Καλλιέργεια, την Εξωστρέφεια, τη Συναισθηματική Σταθερότητα και την Ευσυνειδησία. Επιπρόσθετα, διαπιστώθηκαν θετικές συσχετίσεις με το Ερωτηματολόγιο Ευγνωμοσύνης (GQ-6), την Κλίμακα Υποκειμενικής Ευτυχίας και την Κλίμακα Ικανοποίησης από τη Ζωή. Η βαθμολογία του S-GRAT-Gr βρέθηκε να ερμηνεύει ένα σημαντικό ποσοστό της διακύμανσης του σκορ της Κλίμακας της Ικανοποίησης από τη Ζωή και της Κλίμακας Υποκειμενικής Ευτυχίας, πάνω και πέρα από την επίδραση των διαστάσεων της Προσωπικότητας, καθώς και από το GQ-6. Τα αποτελέσματα υποδεικνύουν ότι η ελληνική εκδοχή του αναθεωρημένου σύντομου Τεστ Ευγνωμοσύνης, Δυσαρέσκειας και Εκτίμησης (S-GRAT-Gr) είναι ένα αξιόπιστο και έγκυρο εργαλείο για την αξιολόγηση της ευγνωμοσύνης στο ελληνικό πλαίσιο.
